Secondary hypogammaglobulinaemia unrelated to Haematological malignancy or haemopoietic stem cell transplant (HSCT)
Condition for which Ig has an emerging therapeutic role.

<table>
<thead>
<tr>
<th>Description and Diagnostic Criteria</th>
</tr>
</thead>
<tbody>
<tr>
<td>An abnormal susceptibility to bacterial infections may arise from acquired hypogammaglobulinaemia that has diverse causes, including haematological malignancies and complications of its treatment (considered in acquired hypogammaglobulinaemia related to haematological malignancy and post haemopoietic stem cell transplantation); protein losing states; malnutrition; thymoma, immunosuppressant therapy; and repeated cycles of B-cell depletion therapy (e.g. rituximab), especially when used with immunosuppressant therapy and in children. In many cases, successful management of the underlying condition will reverse the hypogammaglobulinaemia. However, in some cases, hypogammaglobulinaemia persists and is complicated by recurrent or severe bacterial infections. Secondary hypogammaglobulinaemia may occasionally be complicated by a disseminated enterovirus infection, particularly in patients who have received B cell depletion therapy for a B cell lymphoproliferative disorder.</td>
</tr>
</tbody>
</table>

<table>
<thead>
<tr>
<th>Justification for Evidence Category</th>
</tr>
</thead>
<tbody>
<tr>
<td>Approximately 15 percent of patients who have received a solid organ (heart, lung, kidney) transplant experience secondary hypogammaglobulinaemia with severe IgG deficiency (&lt;4g/L) during the first year after transplantation (Florescu DF. Clin Exp Immunol 2014; 178: 54-6). These patients experience a 3.73-fold increased risk of infection when compared with patients who have normal IgG levels and several studies have shown that IVlg therapy reduces the risk of infection in heart and lung transplant patients (Florescu DF. Clin Exp Immunol 2014; 178: 54-6). There is also evidence that subcutaneous immunoglobulin infusions are safe and effective in lung transplant patients (Shankar T et al. Int Immunopharmacol 2013; 15:752–5).</td>
</tr>
</tbody>
</table>

Hypogammaglobulinaemia may also be a complication of a thymoma (often known as Good’s syndrome). This is usually associated with B cell deficiency. The hypogammaglobulinaemia often increases susceptibility to respiratory tract infections, which are improved by immunoglobulin therapy (Kelesidis T, Yang O. Clinical Immunology 2010; 135: 347–363).

Qualifying Criteria for Ig Therapy

Serum IgG to be measured on two separate occasions (at least one hour apart and at least one sample taken when the patient does not have an active infection). Baseline serum levels of IgA and IgM should be provided to allow assessment of immune recovery at review.

- Significant hypogammaglobulinaemia with serum IgG less than 4g/L (excluding paraprotein) regardless of the frequency and severity of infections
  
  OR

- Serum IgG (excluding paraprotein) greater than 4g/L but less than the lower limit of the age related reference range and at least one life-threatening infection in the last 12 months
  
  OR

- Serum IgG (excluding paraprotein) greater than 4g/L but less the lower limit of the age related reference range with at least two serious infections in the last six months requiring more than standard courses of antibiotics (e.g. Hospitalisation, intravenous or prolonged antibiotic therapy)
  
  OR

- Evidence of impaired antibody production to vaccination in the context of persistent infections affecting long term function such as persistent purulent suppurative otitis media threatening long term hearing

AND

- Underlying cause of hypogammaglobulinaemia cannot be reversed
  
  OR

- Underlying cause of hypogammaglobulinaemia is reversible but reversal is contraindicated

Please note: A diagnosis of bronchiectasis and/or suppurative lung disease must be consistent with the Thoracic Society of Australia and New Zealand (Chang AB et al. 2014).

Initial review is required within six months and ongoing reviews by a specialist at least annually to assess clinical benefit. Documentation of clinical effectiveness is necessary for continuation of Ig therapy.

Cessation of Ig therapy should be considered at least after each 12 months of treatment. If serum IgM and IgA levels are trending upwards and near normal, this may suggest recovery of the immune system and a trial might be considered if the patient is well. Once the patient has normal IgA and IgM levels, the IgG is also likely to be normal and a trial off Ig therapy may be undertaken.

Ig therapy should be extended as required to enable cessation of therapy in September/October, with repeat clinical and/or immunological evaluation before recommencement of therapy.

Antibiotic therapy may be indicated in addition to Immunoglobulin therapy.

Exclusion Criteria

Secondary hypogammaglobulinaemia related to haematological malignant disorders or haemopoietic stem cell transplantation - see Acquired-hypogammaglobulinaemia — haematological malignancy or post HSCT

Transplantation-related immunomodulatory therapy (solid organ transplantation) - see Solid organ transplantation

Disseminated enterovirus infection without hypogammaglobulinaemia
Initial review is required within six months and ongoing reviews by a specialist at least annually to assess clinical benefit. Documentation of clinical effectiveness is necessary for continuation of Ig therapy.

Cessation of Ig therapy should be considered at least after each 12 months of treatment. If serum IgM and IgA levels are trending upwards and near normal, this may suggest recovery of the immune system and a trial might be considered if the patient is well. Once the patient has normal IgA and IgM levels, the IgG is also likely to be normal and a trial off Ig therapy may be undertaken.

Ig therapy should be extended as required to enable cessation of therapy in September/October, with repeat clinical and/or immunological evaluation before recommencement of therapy.

### On review of the initial authorisation period

- Monitoring of serum immunoglobulin levels (IgG, IgM and IgA) and infection history

  AND

- There should be regular consideration of a trial period of cessation of Ig for the purposes of immunological evaluation unless medically contraindicated on safety grounds (for example active bronchiectasis and/or suppurative lung disease, neutropenia, or ongoing immunosuppressant medication) or where there is persistence of the underlying condition that would result in severe hypogammaglobulinaemia in the absence of Ig replacement therapy. Trial cessation is best commenced in September or October.

When IgA and IgM are trending upwards and close to normal and the patient is well, a trial off therapy (in September or October) is considered to allow immunological re-evaluation, or is unless medically contraindicated.

### On review of a continuing authorisation period

- Monitoring of trough or serum immunoglobulin levels (IgG, IgA and IgM) and any history of infection

  AND

- There should be regular consideration of a trial period of cessation of Ig for the purposes of immunological evaluation unless medically contraindicated on safety grounds (for example active bronchiectasis and/or suppurative lung disease, neutropenia, or ongoing immunosuppressant medication) or where there is persistence of the underlying condition that would result in severe hypogammaglobulinaemia in the absence of Ig replacement therapy. Trial cessation is best commenced in September or October.

When IgA and IgM are trending upwards and close to normal and the patient is well, a trial off therapy (in September or October) is considered to allow immunological re-evaluation, or is medically contraindicated.

Please note: A diagnosis of bronchiectasis and/or suppurative lung disease must be consistent with the guideline of the Thoracic Society of Australia and New Zealand (Chang AB et al. 2014).
Dose

- **Loading Dose (IVIg)** - One loading dose of 0.4 g/kg in the first month of therapy (in addition to the maintenance dose) is permitted if the serum IgG level is <4 g/L. This dose is also available as subcutaneous immunoglobulin.

- **Disseminated Enterovirus Dose (IVIg)** - One dose of 2g/kg at any stage is permitted (in addition to the maintenance dose) in the management of disseminated enterovirus infection. This dose is also available as subcutaneous immunoglobulin.

- **Maintenance Dose (IVIg)** - 0.4–0.6g/kg every four weeks or more frequently, to achieve IgG trough level of at least the lower limit of the age-specific serum IgG reference range. More frequent dosing to achieve IgG trough level of up to 9 g/L is permitted if chronic suppurative lung disease is not adequately controlled at an IgG trough level at the lower limit of the age-specific serum IgG reference range. A total dose of up to 1 g/kg may be given over any four week period.

  Subcutaneous administration of immunoglobulin can be considered as an alternative to IVIg.

- **Supplementary Dose (IVIg)** - One additional dose of 0.4 g/kg is permitted at any stage (in addition to the maintenance dose) if the serum IgG level is <4 g/L. This dose is also available as subcutaneous immunoglobulin.

- **Loading Dose (SCIg)** - One loading dose of 0.4 g/kg in the first month of therapy (in addition to the maintenance dose) is permitted if the serum IgG level is <4 g/L. This dose is also available as intravenous immunoglobulin.

- **Disseminated Enterovirus Dose (SCIg)** - One dose of 2g/kg at any stage is permitted (in addition to the maintenance dose) in the management of disseminated enterovirus infection. This dose is also available as intravenous immunoglobulin.

- **Maintenance Dose (SCIg)** - 0.1–0.15g/kg every week or more frequently, to achieve IgG trough level of at least the lower limit of the age-specific serum IgG reference range. More frequent dosing to achieve IgG trough level of up to 9 g/L is permitted if chronic suppurative lung disease is not adequately controlled at an IgG trough level at the lower limit of the age-specific serum IgG reference range. A total dose of up to 1 g/kg may be given over any four week period.

  This dose is also available as intravenous immunoglobulin.

- **Supplementary Dose (SCIg)** - One additional dose of 0.4 g/kg is permitted at any stage (in addition to the maintenance dose) if the serum IgG level is <4 g/L. This dose is also available as intravenous immunoglobulin.

The aim should be to use the lowest dose possible that achieves the appropriate clinical outcome for each patient.

Refer to the current product information sheet for further information on dose, administration and contraindications.
